Nuclear parton distributions

- PDF of the free proton has been studied by many experiments.
- Experiments at vastly different energy scales are connected by **QCD evolution**.
- The PDF of the nucleus and its evolution require further studies.
- The nuclear PDF is defined using a **scaled** momentum fraction

$$x_A = A \frac{p_{\text{parton}}^+}{p_A^+}$$

which allows $x_A > 1$.

- $x_A > 1$ is interesting because it is a purely nuclear effect.
- $x_A > 1$ partons also evolve, and can evolve into $x_A \lesssim 1$ partons.

- 34

イロト イポト イヨト イヨト

Convolution approach

• For moderate-to-high Q^2 (and $x \gtrsim 0.2$), a convolution equation can be derived:

$$f_{i/A}(x_A, Q^2) = \sum_N \int_{x_A}^A d\alpha \int d^2 \mathbf{p}_\perp f_{i/N}^{(b)} \left(\frac{x_A}{\alpha}, \alpha, \mathbf{p}_\perp, Q^2\right) f_{N/A}(\alpha, \mathbf{p}_\perp)$$

- $f_{i/N}^{(b)}\left(\frac{x_A}{\alpha}, \alpha, \mathbf{p}_T, Q^2\right)$ is the **bound nucleon PDF**, which may differ from the free PDF due to medium effects.
- *f*_{N/A}(α, **p**_⊥) is the light cone fraction distribution (LCFD) of the nucleus; it describes nucleonic motion.
- This approach allows $x_A > 1$ depending on how large the LCFD is at $\alpha \gg 1$.
- Measurements of $x_A \gtrsim 1.3$ (meaning $k \gtrsim k_{\text{Fermi}}$) are likely to indicate short range correlations.

・ロト ・ 日 ・ ・ ヨ ・ ・ 日 ・ うへつ

Nuclear light cone fraction distribution

- The LCFD f_{N/A}(α, **p**_⊥) (N = p, n) describes the distribution of nucleons over (scaled) light cone momentum fractions α = A p⁺_N/p⁺_A.
- It satisfies baryon number conservation and momentum conservation:

$$\begin{split} &\sum_{N=p,n} \int_0^A d\alpha \int d^2 \mathbf{p}_\perp f_{N/A}(\alpha,\mathbf{p}_\perp) = A \\ &\sum_{N=p,n} \int_0^A d\alpha \int d^2 \mathbf{p}_T \alpha f_{N/A}(\alpha,\mathbf{p}_\perp) = A \end{split}$$

• It can be decomposed to parts that contribute to j removed nucleons in the final state:

$$f_{N/A}(\alpha, \mathbf{p}_T) = f_{N/A}^{(1)}(\alpha, \mathbf{p}_{\perp}) + f_{N/A}^{(2)}(\alpha, \mathbf{p}_{\perp}) + f_{N/A}^{(3)}(\alpha, \mathbf{p}_{\perp}) + \dots$$

- These contributions add incoherently because the final states are orthogonal.
- $f_{N/A}^{(1)}(\alpha, \mathbf{p}_{\perp})$ (one-nucleon removal) is due to the **mean field**.

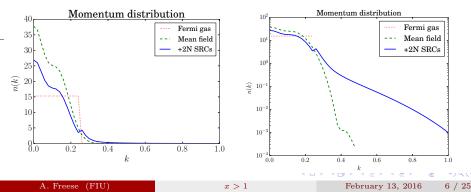

A. Freese (FIU)

End

Short range correlations

- A short range correlation (SRC) occurs when a few nucleons cluster closely, feeling only each others' influence.
- 2N SRCs occur when two nucleons are closely spaced.
- Due to the small distance, their relative momentum is huge—SRCs dominate when $k \gtrsim 250$ MeV (Fermi momentum).
- The result is a fat tail not reproduced by mean field models.

- The behavior of 2N correlations is universal between nuclei.
- There are scaling plateaus for x ≥ 1.4 in the ratio of 2σ_{eA} to Aσ_{ed}
- There is asymmetric momentum sharing between protons and neutrons, suggesting dominance of *pn* pairs in 2N SRCs.
- 2N SRCs behave like a scaled version of the deuteron momentum distribution, so we use

$$f_{N/A}^{(2)}(\alpha, \mathbf{p}_{\perp}) = \frac{a_2(A)}{2\chi_N} \frac{|\psi_d(k)|^2}{\alpha(2-\alpha)} E_k \Theta(k-k_F)$$

where χ_N is the relative fraction of the nucleon type, and

$$k=\sqrt{\frac{m^2+p_{\perp}^2}{\alpha(2-\alpha)}-m^2}$$

is the internal light cone momentum.

Three-nucleon SRCs

- We model 3N SRCs as arising from two subsequent 2N SRCs.
- Model accounts for pn dominance. ۲
- Characteristic topology on right. ٢
- Effective Feynman rules with effective vertices used.

- 3N correlations are expected to exist for $\alpha > 2$ (and $x_A > 2$).
- Experimental status in quasi-elastic scattering experiments is uncertain and contradictory.

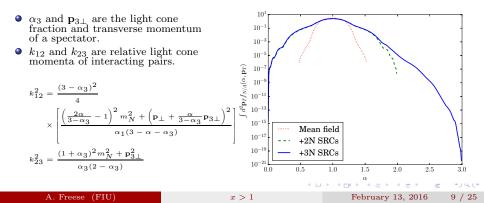

x > 1

End

Three-nucleon SRCs

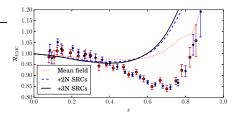

Three-nucleon SRCs are expected to exist for $\alpha > 2$. Our calculation has found:

$$f_{N/A}^{(3)}(\alpha, \mathbf{p}_{\perp}) = \{a_2(A)\}^2 \frac{1}{\alpha} \int \frac{d\alpha_3 d^2 \mathbf{p}_{3\perp}}{\alpha_3(3 - \alpha - \alpha_3)} \left\{ \frac{3 - \alpha_3}{2(2 - \alpha_3)} \right\}^2$$
$$\overline{|\psi_d(k_{23})|^2} \Theta(k_{23} - k_F) \overline{|\psi_d(k_{12})|^2} \Theta(k_{12} - k_F)$$

Collider

Medium Modifications and the EMC effect

- The dip in this ratio has been seen in many experiments.
- First seen by European Muon Collaboration in 1983; called the EMC effect.
- Strength of effect proportional to local nuclear density.
- More modification expected in SRCs; nucleons in SRCs have higher momentum.

• $\mathcal{R} = \frac{2}{A} \frac{\sigma_{eA}(x,Q^2)}{\sigma_{ed}(x,Q^2)}$

• A free nucleon parametrization[†] is used.

End

- f_{N/A}(x, Q²) we've found with a free nucleon PDF gives a bad fit.
- Medium modification is needed.
- The fit with SRCs is worse, so SRCs must be more highly modified.

Color screening model

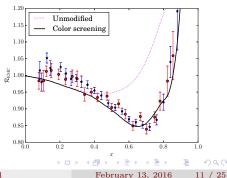

For estimation, I use one example of a medium modification model.

$$f_{i/N}^{(\text{bound})}(x,Q^2,p^2) = \frac{1}{(1+z)^2} f_{i/N}^{(\text{free})}(x,Q^2) \qquad \qquad z = \frac{p^2/m_N^2 + 2\epsilon_A}{\Delta E_A}$$

 ϵ_A is binding energy per nucleon and ΔE_A a characteristic nucleon excitation energy

This is called the color screening model of the EMC effect. cf. Frankfurt and Strikman, Nucl. Phys. **B**250 (1985), 143

- The color screening model fits the EMC data well.
- Sample: ⁵⁶Fe at $Q^2 = 10 \text{ GeV}^2$. Data are from papers by Gomez and Albert.
- The low- $x \leq 0.2$ is due to different dynamics (outside the scope of this research).

Collider

Applications of nuclear PDFs

$$f_{i/A}(x_A, Q^2) = \sum_N \int_{x_A}^A d\alpha \int d^2 \mathbf{p}_\perp f_{i/N}^{(b)} \left(\frac{x_A}{\alpha}, \alpha, \mathbf{p}_\perp, Q^2\right) f_{N/A}(\alpha, \mathbf{p}_\perp)$$

- This formalism for nuclear PDFs has many potential applications:
 - **()** Dijet production in pA collisions (to probe SRCs).
 - \bigcirc eA scattering (inclusive and semi-inclusive) at high (EIC) energies.
 - **③** Drell-Yan processes in pA collisions.
- I will focus on pA collisions at LHC energies here.

cf. AF, Sargsian, and Strikman, Eur. Phys. J. C **75**, 534 (2015) [arXiv:1411.6605] for a detailed account.

SRCe		

Jet kinematics

1

- $pA \rightarrow 2$ jets + X occurs (at leading order) through a two-body to two-body partonic reaction.
- The reaction is described by four kinematic parameters: E_0 (energy per proton), η_3 , η_4 , and p_T .
- From these, the light cone momentum fractions x of the initial partons are:

1
$$x_p = \frac{p_T}{2E_0} (e^{+\eta_3} + e^{+\eta_4})$$
 from proton.

2
$$x_A = \frac{Ap_T}{2ZE_0} (e^{-\eta_3} + e^{-\eta_4})$$
 from nucleus.

• Since the motion of N is unknown and variable, all parameters (e.g. rapidities) are given in the collider reference frame.

э.

イロト イポト イヨト イヨト

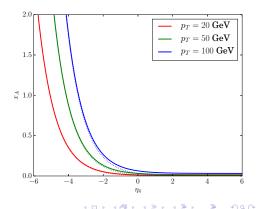

Large x_A at the LHC

The big question is: can we find large x_A at the LHC? (Would indicate SRCs.)

$$x_A = \frac{Ap_T}{2ZE_0} \left(e^{-\eta_3} + e^{-\eta_4} \right)$$

Since $\eta_4 < 0$ and $\eta_3 > 0$ are most likely, we should look for:

- Large p_T .
- Small $|\eta_3|$. Jet from proton should be central.
- Large |η₄|. Jet from nucleus should be forward.

x > 1

14 / 25

End

15 / 25

Dijet cross section

• The cross section for $pA \rightarrow 2$ jets + X factorizes as such:

$$\sigma_{pA} = \sum_{ijkl} \int_0^1 dx_p \int_0^A dx_A f_{i/p}(x_p, Q^2) f_{j/A}(x_A, Q^2) \hat{\sigma}_{ij \to kl}$$

- $Q^2 = p_T^2$ (transverse jet momentum) minimizes NLO, N²LO, etc. corrections.
- This leads to a differential cross section of

$$\frac{d^3\sigma_{pA}}{d\eta_3 d\eta_4 dp_T^2} = \frac{1}{16\pi} \frac{1}{\left(4E_0^2 \frac{Z}{A}\right)^2} \frac{f_{i/p}(x_p, p_T^2)}{x_p} \frac{f_{j/A}(x_A, p_T^2)}{x_A} \frac{\overline{\left|\mathcal{M}_{ij\to kl}\right|^2}}{1+\delta_{kl}}$$

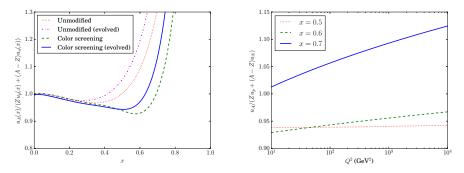

- $\mathcal{M}_{ij \to kl}$ is the tree-level matrix element for a parton-level process.
- The main theoretical issue is the nuclear PDF $f_{j/A}(x, p_T^2)$.
- But this is found by evolving the moderate-Q² nPDF found previously.

A. Freese (FIU)

February 13, 2016

Evolving medium-modified PDFs

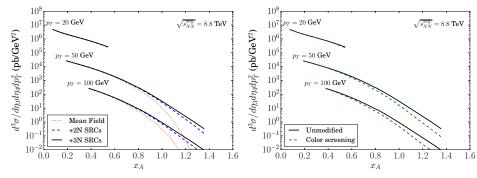

- The color screening model was developed at moderate $Q^2 \sim 10 \text{ GeV}^2$.
- For nuclear PDFs at high Q^2 (e.g. 10^4 GeV^2), use QCD evolution.

The EMC effect evolves little, but fast parton motion evolves a lot.
 Since fast partons lose some of their x, the PDF shifts to the left with evolution.

 16 / 25

Numerical estimates of dijet cross section

Numerical estiamtes of the three-fold cross section

- SRCs significantly increase differential cross section at $x_A \gtrsim 1$.
- Medium modifications suppress cross section at high x_A .

February 13, 2016 17 / 25

Integrated cross sections

We have numerical predictions for the integrated cross section. At 7 TeV per proton,

	Unmodified (SRCs)	Modified (no SRCs)	Modified (SRCs)
All x_A	$58 \ \mu b$	$55 \ \mu b$	$55 \ \mu b$
$0.6 < x_A < 0.7$	$1.7 \ \mu b$	$1.2 \ \mu \mathrm{b}$	$1.3 \ \mu b$
$0.7 < x_A < 0.8$	$0.60 \ \mu \mathrm{b}$	$0.37 \ \mu \mathrm{b}$	$0.43 \ \mu b$
$0.8 < x_A < 0.9$	$0.20 \ \mu b$	$0.11 \ \mu b$	$0.13 \ \mu b$
$0.9 < x_A < 1$	59 nb	20 nb	33 nb
$1 < x_A$	21 nb	3.0 nb	9.3 nb

The expected yield for $x_A > 1$ events at the LHC is 326 events for a month of run time (based on previously achieved luminosity of 35.5 nb⁻¹).

3

Evolution

End

QCD evolution for nuclei

• A slightly modified version of the DGLAP equation is used for nPDFs:

$$\frac{\partial f_{i/A}(x_A, Q^2)}{\partial \log(Q^2)} = \sum_j \frac{\alpha_s}{2\pi} \int_{x_A}^A \frac{dy}{y} f_{j/A}(y, Q^2) P_{ij}\left(\frac{x}{y}\right)$$

where P_{ij} are the Altarelli-Parisi splitting functions.

- The upper integration limit is A rather than 1.
- This means $x_A > 1$ partons at low Q^2 can become $x_A < 1$ partons as Q^2 is increased.
- This also gives a way of making $x_A > 1$ predictions at very high Q^2 using lower- Q^2 , high-precision measurements.

Evolution of structure functions

• Evolution of the structure function

$$F_{2A}(x_A, Q^2) = \sum_i e_i^2 \left(q_{i/A}(x_A, Q^2) + \bar{q}_{i/A}(x_A, Q^2) \right)$$

is relevant to connecting moderate- and high- Q^2 DIS experiments.

• At leading order, and at $x \gtrsim 0.2$ where gluons can be neglected, we have derived a single evolution equation for $F_{2A}(x, Q^2)$:

$$\frac{\partial F_{2A}(x,Q^2)}{\partial \log Q^2} = \frac{\alpha_s}{2\pi} \left\{ 2\left(1 + \frac{4}{3}\log\left(1 - \frac{x}{A}\right)\right) F_{2A}(x,Q^2) + \frac{4}{3} \int_{x/A}^1 \frac{dz}{1-z} \left(\frac{1+z^2}{z} F_{2A}\left(\frac{x}{z},Q^2\right) - 2F_{2A}(x,Q^2)\right) \right\}$$

• This is a **model-independent** way of connecting high- x_A DIS measurements at different Q^2 .

A. Freese (FIU)

February 13, 2016

20 / 25

Evolution

End

Evolving F_{2A}

- $F_{2A}(x, Q^2)$ evolution can connect high-precision JLab measurements on ¹²C to high- Q^2 measurements from the BCDMS and CCFR collaborations.
- JLab measurements from Hall C are done at Q^2 from 2-9 GeV².
- Target mass corrections and higher-twist corrections must be accounted for.
- TMCs are accounted for by ξ -scaling; we evolve $F_{2A}^{LT}(\xi_A, Q^2)$, where:

$$\xi_A = \frac{2x_A}{1 + \sqrt{1 + \frac{4x_A^2 M_A^2}{A^2 Q^2}}}$$

- ξ -scaling as a TMC method minimizes Q^2 dependence of the data.
- HT corrections are accounted for with a fit:

$$F_{2A}^{\rm HT}(\xi_A, Q^2) = \left(1 + \frac{C(\xi_A)}{Q^2}\right) F_{2A}^{\rm LT}(\xi_A, Q^2)$$

• HT fit accommodates any differences between TMC methods.

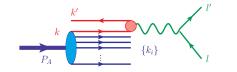

A. Freese (FIU)

Collider

Evolution

ξ -scaling

- ξ_A is a modified Nachtmann variable equal to the true (scaled) momentum fraction of the nuclear parton.
- Breit frame kinematics give

$$k = \left(\frac{\xi_A}{A}P_A^+, 0; \mathbf{0}_\perp\right) \qquad k' = \left(0, \frac{\xi_A}{A}P_A^+; \mathbf{0}_\perp\right)$$
$$P_A = \left(P_A^+, \frac{M_A^2}{P_A^+}; \mathbf{0}_\perp\right)$$
$$\cdot (l - l') = \left(-\frac{\xi_A}{A}P_A^+, \frac{AQ^2}{\xi_A P_A^+}; \mathbf{0}_\perp\right) \equiv q$$

if
$$x_A = AQ^2/(2P_A \cdot q)$$
 is Bjorken x.

 $\xi_A = \frac{2x_A}{1 + \sqrt{1 + \frac{4x_A^2 M_A^2}{A^2 O^2}}}$

DGLAP is based on momentum fractions—evolution should be done in ξ_A .

$$\frac{\partial F_{2A}(\xi_A, Q^2)}{\partial \log Q^2} = \frac{\alpha_s}{2\pi} \left\{ 2 \left(1 + \frac{4}{3} \log \left(1 - \frac{\xi_A}{A} \right) \right) F_{2A}(\xi_A, Q^2) + \frac{4}{3} \int_{\xi_A/A}^1 \frac{dz}{1-z} \left(\frac{1+z^2}{z} F_{2A}\left(\frac{\xi_A}{z}, Q^2 \right) - 2F_{2A}(\xi_A, Q^2) \right) \right\}$$

Higher-twist correction

Fit to JLab Hall C data (cf. PRL105, 212502 (2010))

• Standard HT fitting procedure:

$$F_{2A}^{\rm HT}(\xi_A, Q^2) = \left(1 + \frac{C(\xi_A)}{Q^2}\right) F_{2A}^{\rm LT}(\xi_A, Q^2)$$

• After Accardi et al. (PRD81, 2010) we use

$$C(\xi_A) = c_1 \xi^{c_2} (1 + c_3 \xi)$$

- Leading twist parametrization at $x \ge 0.75$ is $\exp(p_0 + p_1\xi_A + p_2\xi_A^2)$.
- Our best fit $(\chi^2/dof = 10)$:
 - $p_0 = -1.198 \pm 0.781 \qquad c_1 = 5.045 \pm 0.186 \\ p_1 = 0.747 \pm 1.425 \qquad c_2 = 1.390 \pm 0.082 \\ p_2 = -6.643 \pm 0.640 \qquad c_3 = -0.999 \pm 0.010$

Summary and outlook

- nPDF formalism has other potential applications besides pA collisions:
 - O eA scattering (inclusive and semi-inclusive) at high (EIC) energies.
 - **2** Drell-Yan processes in pA and AA collisions.
- Further investigation of F_{2A} evolution must be done.
 - We will perform a fully theoretical calculation for ¹²C to supplement the evolution calculation from JLab measurements.
 - Over the investigation of higher twist is necessary. (Better fit? Better estimates?)
 - We need more data over a greater range of Q^2 at x > 1. Can 12 GeV JLab and EIC provide?
