

## PHZ 3113 – PROBLEM SET 6

- 1) The function  $f(t)$  is defined by  $f(t)=\exp(-at)$  for  $t \geq 0$ .
  - a) Derive the Fourier *sine* and Fourier *cosine* transformations of this function.
  - b) Using the results of part a, show that the function  $\exp(-at)$  can be represented by either of the integrals below, where the integration ranges are from 0 to  $\infty$ .

$$\exp(-at) = (2/\pi) \int_0^{\infty} \omega \sin(\omega t) / (a^2 + \omega^2) d\omega$$

$$\exp(-at) = (2a/\pi) \int_0^{\infty} \cos(\omega t) / (a^2 + \omega^2) d\omega$$

- 2) **Text Problem 5.2** – in part a, note that if you make a change of variable in the Fourier transform integral from  $x$  to  $x'=x+a$ , the function  $f(x)$  will not be affected due to the periodicity assumption. The result in part (c) can also be easily derived by making a change of variable.
- 3) Consider the differential equation,  $-D d^2f/dx^2 + K^2D f(x) = Q\delta(x)$ , where  $K$ ,  $D$ , and  $Q$  are constants, and  $\delta(x)$  is the Dirac  $\delta$ -function.
  - a) Derive the equation satisfied by the Fourier transform of  $f(x)$  and solve it.
  - b) Perform the inverse Fourier transform to obtain the function  $f(x)$  that satisfies the original differential equation. Note that since the Fourier transform is symmetric, the relevant transform is the cosine one. For  $x > 0$ , the required integral is given in problem 1. For  $x < 0$ , just replace  $x$  by  $-x$ .
- 4) **Text Problem 5.1** – note that the function is *symmetric*, so that a cosine Fourier transformation is appropriate.

- 5) The function  $q(x,t)$  satisfies the differential equation  $\partial^2 q / \partial x^2 = \partial q / \partial t$ . Define the function  $Q(k,t)$  to be the Fourier transform of  $q$  with respect to  $x$ .
- a) Derive the differential equation satisfied by  $Q$  and show that its solution has the form  $Q(k,t) = A \exp(-k^2 t)$ , where  $A$  is a constant.
- b) Suppose that at time  $t=0$ , the function  $q$  is given by  $q(x,t=0) = S \delta(x)$ , where  $\delta$  is the Dirac  $\delta$ -function, and  $S$  is a constant. Show that this condition requires that the constant  $A$  be equal to  $S/\sqrt{2\pi}$ .
- c) By evaluating the inverse Fourier transform of  $Q$ , find the function  $q(x,t)$  that satisfies the original differential equation with the initial condition given in part b. To carry out the required integral, define a new variable  $u$  such that  $u^2 = k^2 t - ikx - x^2/4t$  and make use of the result  $\int \exp(-u^2) du = \sqrt{\pi}$ , where the integral is from  $-\infty$  to  $+\infty$ .
- 6) **Text Problem 5.7** – note that the function is *symmetric*, so that a cosine Fourier transformation is appropriate. In evaluating the convolution integral, you will have to determine the region over which the product integrand is non-zero.
- 7) **Text Problem 5.14** – note that the result can be obtained using Parseval's theorem.

- 8) Consider the function  $f(x)$  defined by the relations

$$f(x) = \begin{cases} 1 - |x|/2 & \text{for } -2 \leq x \leq 2 \\ 0 & \text{otherwise} \end{cases}$$

- a) Noting that the function is *symmetric*, derive the Fourier cosine transform of the function.
- b) Using the result of part a and Parseval's theorem for Fourier transforms, show that

$$\int (\sin k/k)^4 dk = 2\pi/3$$

where the integral ranges from  $-\infty$  to  $+\infty$ .

9) The three dimensional Fourier transform of the function  $f(\mathbf{r})$  is given by

$$F(\mathbf{k}) = 1 / [(2\pi)^3 k^2]$$

where  $k$  is the magnitude of the vector  $\mathbf{k}$ . Show that  $f(\mathbf{r}) = 1/(4\pi r)$ , where  $r$  is the magnitude of the position vector  $\mathbf{r}$ . The required three dimensional integral can be most easily evaluated using spherical coordinates with the  $k$ -space  $z$ -axis chosen in the direction of the position vector  $\mathbf{r}$ . To perform the  $k$ -space radial integral, you will need the result

$$\int \sin u/u \, du = \pi/2$$

where the integral ranges from  $0$  to  $\infty$ .
